Problem 3.
Draw a picture
Original mixture
$p=760 \mathrm{~mm} \mathrm{Hg}$
$20^{\circ} \mathrm{C}$
$\mathrm{N}_{2}$
$\mathrm{H}_{2} \mathrm{O}$

OOOOOOO
dry drying agent

Final
$p=745 \mathrm{~mm} \mathrm{Hg}$ $20^{\circ} \mathrm{C}$
$\mathrm{N}_{2}$

## 

drying agent with 0.150 g adsorbed $\mathrm{H}_{2} \mathrm{O}$

Question: (a) mole percent $\mathrm{N}_{2}=$ ?
(b) $V=$ ?

Principles and $\operatorname{Definitions:~}$
Definition of partial pressure: $p_{\mathrm{N} 2}=x_{\mathrm{N} 2} p$
Dalton's law of partial pressures:
$p_{\mathrm{N} 2}+p_{\mathrm{H} 2 \mathrm{O}}=p$

$$
p_{\mathrm{N} 2}=p
$$

Assume the gases behave ideally: $\quad p V=n R T$
For an ideal gas the partial pressure of a gas in a mixture of gases is the pressure that would be exerted by the gas if it had been alone by itself in the same volume and temperature.

## Solution:

In the same volume $V=$ unknown and same $T=(20+273.15) \mathrm{K}, p_{\mathrm{N} 2}=p=745 \mathrm{~mm} \mathrm{Hg}$.
Therefore, $p_{\mathrm{N} 2}=745 \mathrm{~mm} \mathrm{Hg}$ in the original mixture (and $p_{\mathrm{H} 2 \mathrm{O}}=760-745=15 \mathrm{~mm} \mathrm{Hg}$ ).
From the definition of partial pressure:
$\left\{p_{\mathrm{N} 2}=x_{\mathrm{N} 2} p\right\}$ applies in the original mixture, where $p_{\mathrm{N} 2}=745 \mathrm{~mm} \mathrm{Hg}$ and $p=760 \mathrm{~mm} \mathrm{Hg}$, from which equation we find $x_{\mathrm{N} 2}=p_{\mathrm{N} 2} / p=745 / 760=0.980$
(a): $100 \times x_{N 2}=98 \%$
(b) Mass of water vapor in original mixture $=$ increase in weight of the drying agent $=0.150 \mathrm{~g}$ $\mathrm{H}_{2} \mathrm{O}$. Assume water vapor behaves ideally in the original mixture:
$p_{\mathrm{H} 2 \mathrm{O}}=15 \mathrm{~mm} \mathrm{Hg}$, which is the pressure $0.150 \mathrm{~g} \mathrm{H}_{2} \mathrm{O}$ would exert if by itself in the volume V and temperature $T=293.15 \mathrm{~K}$. Substitute these data into

$$
\begin{gathered}
V=n R T / p \text { to obtain } V=\left(0.150 \mathrm{~g} / 18.0 \mathrm{~g} \mathrm{~mol}^{-1}\right) \times 8.20578 \times 10^{-2} \mathrm{~L} \text { atm } \mathrm{K}^{-1} \mathrm{~mol}^{-1} \times 293.15 \mathrm{~K} \\
\div(15 \mathrm{~mm} \mathrm{Hg} \times 1 \mathrm{~atm} / 760 \mathrm{~mm} \mathrm{Hg})
\end{gathered}
$$

$$
=10.2 \mathrm{~L}
$$

Not asked for, but we can also find the amount of $\mathrm{N}_{2}$ :
(1) We can use the ideal gas law in the final picture:

$$
\begin{aligned}
& \qquad \begin{aligned}
& n=p V / R T=745 \mathrm{~mm} \mathrm{Hg} \times(1 \mathrm{~atm} / 760 \mathrm{~mm} \mathrm{Hg}) \times 10.2 \mathrm{~L} \\
& \div\left\{8.20578 \times 10^{-2} \mathrm{Latm} \mathrm{~K}^{-1} \mathrm{~mol}^{-1} \times 293.15 \mathrm{~K}\right\}
\end{aligned} \\
& =0.414 \mathrm{~mol} \mathrm{~N}_{2}
\end{aligned}
$$

3. A mixture of nitrogen and water vapor is admitted to a flask which contains a solid drying agent. Immediately after admission, the pressure in the flask is 760 mm . After standing some hours, the pressure reaches a steady value of 745 mm . (a) Calculate the composition, in mole percent, of the original mixture. (b) If the experiment is done at $20^{\circ} \mathrm{C}$ and the drying agent increase in weight by 0.150 g what is the volume of the flask? (The volume occupied by the drying agent may be ignored.)

Problem 4.

## Draw a picture

Original mixture

| $\begin{aligned} & \mathrm{O}_{2} \\ & \mathrm{H}_{2} \end{aligned}$ | 00000 hot CuO drying agent |  |
| :---: | :---: | :---: |

Question: $\quad$ In original mixture, $x_{02}=$ ? $x_{\mathrm{H} 2}=$ ?

## Principles and Definitions:

Chemical reactions:
$\mathrm{O}_{2}+\mathrm{CuO} \rightarrow$ no reaction
$\mathrm{H}_{2}+\mathrm{CuO} \rightarrow \mathrm{Cu}+\mathrm{H}_{2} \mathrm{O} \quad$ amount of Cu formed is stoichiometric - based on moles $\mathrm{H}_{2}$ reacted.
$1 / 2 \mathrm{O}_{2}+\mathrm{Cu} \rightarrow \mathrm{CuO} \quad$ amount of $\mathrm{O}_{2}$ removed is stoichiometric - based on moles Cu present, which in turn, is the same as moles $\mathrm{H}_{2}$ reacted.
Definition of mole fraction: $x_{\mathrm{O} 2}=n_{\mathrm{O} 2} /\left(n_{\mathrm{O} 2}+n_{\mathrm{H} 2}\right)$
Assume ideal gas behavior:
$p V=n R T$

## Solution:

Let $n=$ original no. of moles of gas $=n_{\mathrm{O} 2}+n_{\mathrm{H} 2}$
$n=p V / R T=750 \mathrm{~mm} \mathrm{Hg} \times(1 \mathrm{~atm} / 760 \mathrm{~mm} \mathrm{Hg}) \times 100 \mathrm{~cm}^{3} \mathrm{~L} \times\left(1 \mathrm{~L} / 10^{3} \mathrm{~cm}^{3}\right)$ $\div\left\{8.20578 \times 10^{-2} \mathrm{~L} \mathrm{~atm} \mathrm{~K} \mathrm{~mol}^{-1} \times(25+273.15) \mathrm{K}\right\}$
$=4.034 \times 10^{-3}$ moles gas
$x_{\mathrm{H} 2}+x_{\mathrm{O} 2}=1$
moles $\mathrm{O}_{2}$ in original $=x_{02}\left(4.034 \times 10^{-3}\right.$ moles $)$
moles $\mathrm{H}_{2}$ in original $=x_{\mathrm{H} 2}\left(4.034 \times 10^{-3}\right.$ moles $)$
After reaction, no. of moles of $\mathrm{O}_{2}$ gas $=p V / R T$

$$
\begin{aligned}
& =750 \mathrm{~mm} \mathrm{Hg} \times(\mathrm{I} \mathrm{~atm} / 760 \mathrm{~mm} \mathrm{Hg}) \times 84.5 \mathrm{~cm}^{3} \mathrm{~L} \times\left(1 \mathrm{~L} / 10^{3} \mathrm{~cm}^{3}\right) \\
& \div\left\{8.20578 \times 10^{-2} \mathrm{~L} \mathrm{~atm} \mathrm{~K} \mathrm{Kol}^{-1} \times(25+273.15) \mathrm{K}\right\}
\end{aligned}
$$

$=3.408 \times 10^{-3}$ moles $\mathrm{O}_{2}$ gas are left

Let $y=$ moles of $\mathrm{H}_{2}$ reacted $\begin{array}{ll}\mathrm{H}_{2}+\mathrm{CuO} \rightarrow \mathrm{Cu}+\mathrm{H}_{2} \mathrm{O} \\ y & y \quad y \quad y \text { moles }\end{array}$
This amount of Cu then reacts : $\quad 1 / 2 \mathrm{O}_{2}+\mathrm{Cu} \rightarrow \mathrm{CuO}$
$1 / 2 y \quad y \quad y \quad$ using up $1 / 2 y$ moles of $\mathrm{O}_{2}$.
From reaction (1), moles of $\mathrm{H}_{2}=n_{\mathrm{H} 2}=x_{\mathrm{H} 2}\left(4.034 \times 10^{-3}\right.$ moles $)=y$

$$
\text { or } X_{\mathrm{H} 2}=y /\left(4.034 \times 10^{-3} \text { moles }\right)
$$

Because of reaction (2), moles of $\mathrm{O}_{2}$ left $=x_{\mathrm{O} 2}\left(4.034 \times 10^{-3} \mathrm{moles}\right)-1 / 2 y=3.408 \times 10^{-3} \mathrm{moles}$

$$
\text { or } x_{02}=\left[3.408 \times 10^{-3}+1 / 2 y\right] /\left(4.034 \times 10^{-3}\right)
$$

Since $x_{\mathrm{H} 2}+x_{\mathrm{O} 2}=1$
or

$$
y /\left(4.034 \times 10^{-3} \text { moles }\right)+\left[3.408 \times 10^{-3}+1 / 2 y\right] /\left(4.034 \times 10^{-3}\right)=1
$$

$$
(3 / 2) y=(4.034-3.408) \times 10^{-3}
$$

$$
y=4.173 \times 10^{-4} \text { moles }
$$

Substitute into $x_{\mathrm{H}_{2}}=y /\left(4.034 \times 10^{-3}\right.$ moles $)$ to get $\mathrm{X}_{\mathrm{H} 2}=0.103$

$$
\therefore x_{\mathrm{O} 2}=\left(1-x_{\mathrm{H} 2}\right)=0.897
$$

4. A mixture of oxygen and hydrogen is analyzed by passing it over hot copper oxide and through a drying tube. Hydrogen reduces the CuO to metallic Cu . Oxygen then reoxidizes the copper back to $\mathrm{CuO} .100 \mathrm{~cm}^{3}$ of the mixture measured at $25^{\circ} \mathrm{C}$ and 750 mm yields $84.5 \mathrm{~cm}^{3}$ of dry oxygen measured at $25^{\circ} \mathrm{C}$ and 750 mm after passage over CuO and the drying agent. What is the original composition of the mixture? \{Hint: First write balanced chemical equations for the reactions.\}

## Problem 5.

## Draw a picture

At ground level $(z=0)$
Atmosphere: $p=1 \mathrm{~atm}$
$V=10^{4} \mathrm{~m}^{3} \mathrm{He}$
$T=(20+273.15) \mathrm{K}$ ain $\uparrow$ 个 ain
mass of empty balloon $=1.3 \times 10^{6} \mathrm{~g}$
Total mass $=m_{\text {balloon }}+m_{\text {load }}+m_{\text {He }}$

$$
\text { At } z=h=?
$$

$$
p=\boldsymbol{?} \mathrm{atm}
$$

$$
V=10^{4} \mathrm{~m}^{3} \mathrm{He}
$$

$$
T=(20+273.15) \mathrm{K}
$$

$$
\text { mass of empty balloon }=1.3 \times 10^{6} \mathrm{~g}
$$

Total mass $=m_{\text {balloon }}+0.80\left(m_{\text {load }}\right)+m_{\text {He }}$

## Question:

$$
h=?
$$

## Principles and Definitions:

1. Archimedes principle : At equilibrium, the surrounding fluid (air, in this case) supports a body (balloon + load it is carrying) whose weight is equal to the weight of the displaced fluid.
This means:
at height $Z=h$ equilibrium is reached when mass of displaced air $=m_{\text {balloon }}+0.80\left(m_{\text {load }}\right)+m_{\mathrm{He}}$ at ground level $z=0$, equilibrium is reached when mass of displaced air $=m_{\text {balloon }}+m_{\text {load }}+m_{\mathrm{He}}$
2. Barometric formula: $\rho / \rho_{0}=\rho / \rho_{0}=\exp [-M g h / R T]$
3. Assume ideal gas behavior for both air and $\mathrm{He}: p V=n R T$ or units: $\mathrm{J} \equiv \mathrm{kg} \mathrm{m}^{2} \mathrm{~s}^{-2}$
Assume that we can neglect the volume of air displaced by the load in comparison to the volume of the balloon.

## Solution:

At ground level, the mass of displaced air $=\rho_{0} V \quad$ At $h$, the mass of displaced air $=\rho V$
The equilibrium conditions are:
we obtain

From eq. (1), we obtain
$\therefore m_{\text {load }}=1.1972 \times 10^{7} \mathrm{~g}-\left[1.3 \times 10^{6} \mathrm{~g}+1.663 \times 10^{6} \mathrm{~g}\right]=9.01 \times 10^{6} \mathrm{~g}$
Substitute this into eq. (3),

$$
\begin{aligned}
\rho / \rho_{0} & =\left[1.3 \times 10^{6}+1.663 \times 10^{6}+0.80 \times 9.01 \times 10^{6}\right] /\left[1.3 \times 10^{6}+1.663 \times 10^{6}+9.01 \times 10^{6}\right]=0.85 \\
\rho / \rho_{0} & =0.85=\exp [-M g h / R T] \\
& =\exp \left[28.8 \mathrm{~g} \mathrm{~mol}^{-1} \times 1 \mathrm{~kg} / 10^{3} \mathrm{~g} \times 9.80665 \mathrm{~m} \mathrm{~s}^{-2} \times h \mathrm{~m} / 8.31451 \mathrm{~J} \mathrm{~K}^{-1} \mathrm{~mol}^{-1} \times 293.15 \mathrm{~K}\right] \\
0.85 & =\exp \left[1.159 \times 10^{-4} h\right] \quad \text { or } 1.159 \times 10^{-4} h=\ln (0.85), \quad h=1.402 \times 10^{3} \mathrm{~m} \quad \text { Answer }
\end{aligned}
$$

$$
\begin{align*}
& m_{\text {balloon }}+m_{\text {load }}+m_{\mathrm{He}}=\rho_{0} \mathrm{~V} \text { (1) and } m_{\text {balloon }}+0.80\left(m_{\text {load }}\right)+m_{\mathrm{He}}=\rho \mathrm{V}  \tag{2}\\
& \text { Eq. (2) } \div \text { Eq. (1): } \quad \rho / \rho_{0}=\left[m_{\text {balloon }}+0.80\left(m_{\text {load }}\right)+m_{\text {He }}\right] /\left[m_{\text {balloon }}+m_{\text {load }}+m_{\text {He }}\right]  \tag{3}\\
& m_{\mathrm{He}}=\mathrm{M}_{\mathrm{He}}(p V / R T) \\
& =4.0 \mathrm{~g} \mathrm{~mol}^{-1} \times 1 \mathrm{~atm} \times 10^{4} \mathrm{~m}^{3} \times\left(10^{3} \mathrm{~L} / 1 \mathrm{~m}^{3}\right) \\
& \div\left[8.20578 \times 10^{-2} \mathrm{~L} \mathrm{~atm} \mathrm{~K}^{-1} \mathrm{~mol}^{-1} \times 293.15 \mathrm{~K}\right]=1.663 \times 10^{6} \mathrm{~g} \\
& \rho_{0} V=m_{\text {air }} \\
& =28.8 \mathrm{~g} \mathrm{~mol}^{-1} \times 1 \mathrm{~atm} \times 10^{4} \mathrm{~m}^{3} \times\left(10^{3} \mathrm{~L} / 1 \mathrm{~m}^{3}\right) \\
& \div\left[8.20578 \times 10^{-2} \mathrm{~L} \mathrm{~atm} \mathrm{~K}^{-1} \mathrm{~mol}^{-1} \times 293.15 \mathrm{~K}\right] \quad=1.1972 \times 10^{7} \mathrm{~g} \\
& =28.8 \mathrm{~g} \mathrm{~mol}^{-1} \times 1 \mathrm{~atm} \times 10^{4} \mathrm{~m}^{3} \times\left(10^{3} \mathrm{~L} / 1 \mathrm{~m}^{3}\right)
\end{align*}
$$

Approximate method: If $m_{\text {balloon }}+m_{\mathrm{He}} \ll m_{\mathrm{load}}$ then, the equilibrium conditions are:

$$
\begin{gathered}
m_{\text {load }} \approx \rho_{0} V \\
\rho / \rho_{0} \approx 0.80=\exp [-M \mathrm{gh} / R T] \\
=\exp \left[28.8 \mathrm{~g} \mathrm{~mol}^{-1} \times 1 \mathrm{~kg} / 10^{3} \mathrm{~g} \times 9.80665 \mathrm{~m} \mathrm{~s}^{-2} \times h \mathrm{~m} / 8.31451 \mathrm{~J} \mathrm{~K}^{-1} \mathrm{~mol}^{-1} \times 293.15 \mathrm{~K}\right] \\
0.80 \approx \exp \left[1.159 \times 10^{-4} h\right] \quad \text { or } \quad 1.159 \times 10^{-4} h \approx \ln (0.80), \quad \therefore h \approx 1.926 \times 10^{3} \mathrm{~m}
\end{gathered}
$$

5. A balloon having a capacity of $10,000 \mathrm{~m}^{3}$ is filled with helium at $20^{\circ} \mathrm{C}$ and 1 atm pressure. If the balloon is loaded with $80 \%$ of the load that it can lift at ground level, at what height will the balloon come to rest? Assume that the volume of the balloon is constant, the atmosphere isothermal, $20^{\circ} \mathrm{C}$; the molecular weight of air is 28.8 and the ground level pressure is 1 atm . The mass of the balloon is $1.3 \times 10^{6}$ g.
6. Composition of the atmosphere as function of height above ground level

| Equation | Basis for the equation | Eq. \# |
| :---: | :---: | :---: |
| $\mathrm{p}_{\mathrm{i}} / \mathrm{p}_{\mathrm{i} 0}=\exp \left[-\mathrm{M}_{\mathrm{i}} \mathrm{~g} \mathrm{z} / \mathrm{RT}\right]$ $\text { joule }=\mathrm{kg} \mathrm{~m}^{2} \mathrm{~s}^{-2}$ <br> use M in $\mathrm{kg} \mathrm{mol}^{-1}$ and z in m or equivalently, use M in $\mathrm{g} \mathrm{mol}^{-1}$ and z in km with $\mathrm{g}=9.8 \mathrm{~m} \mathrm{~s}^{-2}$ <br> so that Mgz is in $\mathrm{J} \mathrm{mol}^{-1}$ thus use $\mathrm{R}=8.31451 \mathrm{~J} \mathrm{~mol}^{-1} \mathrm{~K}^{-1}$ | Relation of partial pressure of a gas at height $Z$ relative to its partial pressure at ground level depends on molar mass of gas, as derived in lecture notes part 1 <br> RT has units of energy, has to have same units as Mgz Use $\mathrm{g}=9.8 \mathrm{~m} \mathrm{~s}^{-2}$ | 1 |

Use the barometirc formula in Eq 1 for how number density drops off with height Integrate over all these \(\mathrm{dN}_{\mathrm{i}}\) \\
This is the same total number of molecules as for a uniform partial pressure at ground level through a height \(\mathrm{RT} / \mathrm{M}_{\mathrm{i}} \mathrm{g}\) and no molecules above this height. (That is, Eq 8 is the same as Eq 4)
