1. (b) For equilibrium to be established (no more net influx of water from the water side through the membrane to the glucose solution side), the chemical potential of water should be the same on both sides of the membrane.
On the solution side of the membrane there is an additional pressure $\pi$ arising from the column of solution. The osmotic pressure is the additional pressure that needs to be applied to the solution side to achieve equilibrium with the pure solvent at pressure $p$.

For the ideal solution, we can use mole fraction instead of activity
